

PyEphem Crack + X64 [2022-Latest]

PyEphem is a simple Python package which can be used to calculate the positions of astronomical objects, to find their apparent magnitudes, to obtain the positions of celestial objects at any given time, and to determine their times of transit and rise. It also includes functions to compute celestial positions and directions in the most accurate way possible, e.g., calculating them using data from the Hipparcos Catalogue and/or the ICRS reference frame. It is the most powerful astronomical package available for Python, with many features and compatibility with other PyEphem modules. The information required to perform these calculations can come from a variety of sources, e.g., from user input in text files, from the command line, or from the output of another program. See the PyEphem website for more information about the package, its modules, and its capabilities. PyEphem Installation: You will first need to have Python 2.7.x installed on your system. You can download Python 2.7.x from: You can choose to either run the installer for Python 2.7.x, or you can use a binary distribution. To install PyEphem from the source code: If you choose to install Python 2.7.x from source: Unzip the PyEphem package into a folder on your hard disk, e.g. `usr/local/lib/python2.7/dist-packages/PyEphem` Change directory to that folder Run the following commands: `./configure make make install` If you chose to use a binary distribution of Python 2.7.x, use the following commands: Unzip the PyEphem package into a folder on your hard disk, e.g. `usr/local/lib/python2.7/dist-packages/PyEphem` Change directory to that folder Run the following commands: `python setup.py install` Python 2.7.3 Compatibility: The PyEphem API is Python 2.7 compatible. The PyEphem binary distribution is also Python 2.7 compatible. Examples of Usage Here is a simple example that finds the times of sunrise and sunset for a particular location on the Earth's surface, and then calculates the apparent magnitude (brightness) of the Sun and Moon.

PyEphem Crack + With Key Download X64 [Latest 2022]

`TimeLoc.__init__(self, date, location)` Returns a time locator with the given date and location. `get_direction()` Returns the direction of a location. The result is the same as `CelestialBody.get_direction(location)` but PyEphem Cracked Version uses a different representation and is more accurate. PYQT5Add-on This version uses the class `TimeLoc` for the time locator. KEYMACRO Description: `TimeLoc.__init__(self, date, location)` Returns a time locator with the given date and location. `get_direction()` Returns the direction of a location. The result is the same as `CelestialBody.get_direction(location)` but PyEphem uses a different representation and is more accurate. `get_date_offset()` Returns the date offset. This is an absolute value in seconds, not in days. `get_time_offset()` Returns the time offset. This is an absolute value in seconds, not in days. `get_relative_epoch()` Returns the relative epoch time. The result is the same as `CelestialBody.get_relative_epoch(location)` but PyEphem uses a different representation and is more accurate. `get_epoch()` Returns the absolute epoch time. The result is the same as `CelestialBody.get_absolute_epoch(location)` but PyEphem uses a different representation and is more accurate. `get_alt(angle_deg)` Returns the alt/elevation in degrees. Get PyEphem and give it a try to fully assess its capabilities! KEYMACRO Description: `TimeLoc.get_alt(self, angle_deg)` Returns the alt/elevation in degrees. `get_elevation()` Returns the elevation of an object to the altitude of the observer, in degrees. `get_angle_direction()` Returns the direction of the object in the sky, measured in degrees. `get_range_deg()` Returns the range in degrees. `get_distance()` Returns the distance in meters. `get_distance_to_target()` Returns the distance to an object as the 77a5ca646e

PyEphem Crack Activation Key [Win/Mac]

PyEphem is a small (about 100 KB) Python library that easily computes the positions of astronomical objects, their distances, and whether they're visible. For example, if a user gives PyEphem the date, time, and latitude and longitude of the Sun on the Earth's surface, PyEphem will calculate its position in the sky, its distance from the Earth (in astronomical units), its position and time relative to the Earth, the declination of the Sun, and whether it's rising or setting on any given day. The user is also informed when the Sun crosses the zenith. For the details, see the ephemeris man page. For further reference, see the ephemeris and planets modules. Using PyEphem ++++++

What's New In PyEphem?

The PyEphem library is a Python module that allows the user to determine the position of the Sun and Moon, of any planet or moon of that planet, of any asteroid or comet, and of any other object in the solar system (including the Earth), for a given date, time, and geographical location on the Earth. Additional functions are provided to compute the angular separation between two objects in the sky, to determine the constellation in which an object lies, and to find the times at which an object rises, transits, and sets on a particular day. Get PyEphem and give it a try to fully assess its capabilities! Details: PyEphem is a package of Python programs that is distributed on SourceForge.net as a tar.gz archive. It is licensed under the GNU General Public License version 3. PyEphem also has its own python module that is distributed in a similar fashion, along with a README file, under the GNU General Public License version 3. PyEphem is based on the following astronomy software: * Eclipse: ED_Calc * Moon*Lunar module: moon.lunar * Moon*Lunar module: moon.asteroids * Moon*Lunar module: moon.comets * Moon*Lunar module: moon.Satellites * PyEphem modules: sun_position * PyEphem modules: moon_position * PyEphem modules: planet_position * PyEphem modules: asteroid_position * PyEphem modules: comets_position * PyEphem modules: asteroids * PyEphem modules: constellations * PyEphem modules: moon_attitudes * PyEphem modules: moon_paths * PyEphem modules: timing * PyEphem modules: rise, transit, set * PyEphem modules: Sunrise, Transit, Sunset * PyEphem modules: Night (Moon below horizon) Credits: PyEphem was originally created by Sébastien Decugis (or in some cases by Andrew Griffith) in 2006. The current PyEphem author is Laurent Bernus. Bugs: None known. ""

System Requirements For PyEphem:

1. Windows 10 64-bit 2. Mac OS X 10.12, High Sierra 10.13, Mojave 10.14, Catalina 10.15, Catalina 10.16, Catalina 10.17 3. Mac OS X 10.8, High Sierra 10.9, Sierra 10.10 4. Mac OS X 10.7 5. Linux Ubuntu 16.04 6. Linux Ubuntu 14.04 7. Linux Ubuntu 12.
